

02424 Assignment 2, 2022

This is the second of three mandatory assignments for the course 02424. It must be handed in using the Learn (time and date is given there and in the general course plan in Learn). The submissions must contain one collected attached file in Portable Document Format (PDF), other document formats will not be accepted.

The report of each assignment must be prepared in groups of 3, and the final grading will be based on the reports and the (individual) oral exam.

When writing the report please explain carefully what you did in each step, back up your statements with quantitative measures when possible, explicitly write down all models used in mathematical notation, and last but not least keep it short and concise.

Ozone model

In this part you will model ozone concentration in Los Angeles, the data is uploaded to Learn along with this assignment, but is also included in the package `gclus`, and more information on the data can be obtained from there, e.g.

```
library(gclus)
data(ozone)
head(ozone)
```

##	Ozone	Temp	InvHt	Pres	Vis	Hgt	Hum	InvTmp	Wind
## 1	3	40	2693	-25	250	5710	28	47.66	4
## 2	5	45	590	-24	100	5700	37	55.04	3
## 3	5	54	1450	25	60	5760	51	57.02	3
## 4	6	35	1568	15	60	5720	69	53.78	4
## 5	4	45	2631	-33	100	5790	19	54.14	6
## 6	4	55	554	-28	250	5790	25	64.76	3

Part 1

You should only consider additive and linear effects

1. Make a short presentation of the data
2. Fit a general linear model, and perform a residual analysis (you may consider transformations of the dependent variable)
3. Fit at least two different (sensible) generalized linear models to the data (you do not have to report residual plots of all the models here), and compare these models by quantitative numbers (you can play around with the distribution assumption and the link function).
4. Compare the model under question 2 and the model chosen from question 3, which one would you prefer (if you choose a quantitative measure you may need to take the transformation into account)?
5. Present the final model.

Clothing insulation level: Count data

In this part you should analyze the dataset `clo.count` the data set is constructed using the data you used in the first assignment, but `clo` now contain the number of times that each subject change clothing insulation level during a day, total time of observation (`time`), number of observations during the day (`nobs`), the sex of the subject (`sex`), and average outdoor and indoor operating temperature (`tOut`, and `tInOp`), during the day.

1. Develop a generalized linear model, based on the Binomial distribution, when ignoring `subjId` and `day`
2. Develop a generalized linear model, based on the Poisson distribution, when ignoring `subjId` and `day` (You should consider including an offset in your model).
3. Discuss the interpretation of the two models you fitted above.

Fan Speed

In the part you should analyze the dataset `CeilingFan.csv`. The dataset consist of a thermal sensation vote (TSV) on a 3 level scale, the speed of a fan `fanspeed` (also 3 levels), type of fan `fanType`, and a subject identifier `subjId` (which you should ignore here).

1. Using the usual contingency table test if independence between TSV and `fanSpeed`, can be assumed.
2. Using the package `ordinal` construct 2 models to test the same hypothesis as in 1 (but with the method `anova`)
3. Fit and develop a model for TSV as a function of `fanSpeed` and `fanType` (hint you may consult Example 4.12 of the textbook).
4. Present the result, e.g. interpretation of the parameters and/or some visual presentation.
